

Staged Build AI & Approval Bridge Spec

This document details our architectural alignment blueprint for mirroring live communication streams into a safe staging dashboard. It establishes an explicit human-in-the-loop gatekeeper, allowing incoming instructions from alternative external environments to compile securely but execute only upon a verified manual approval step.

1. System Ecosystem Alignment: My Spec vs. Simpee

Since both systems handle separate ends of your workspace environment, laying them side-by-side allows us to evaluate exactly where data transforms and where execution permissions are strictly held:

SIMPEE ENVIRONMENT SPEC	MY BASE44 ENVIRONMENT SPEC
Role: Communication Interface Provider. • Acts as the live conversational engine handling your initial feature ideas and messaging text structures. • Pushes out rapid text outputs to Make.com webhooks but has zero native authority to modify your production application code or change database logic.	Role: Staging Database & Core Compiler. • Acts as the target data manager and application builder environment. • Catches the raw mirrored instructions stream, converts them into file logic inside a staging table, and renders a secure mobile/desktop approval interface.

2. Complete Data Flow Architecture

- Data Ingest:** Conversational instructions step out of your active chat setup and hit the Make.com routing endpoint URL.
- Data Isolation:** Instead of executing immediately, the webhook writes the payload straight to an internal table collection named `pending_build_instructions` inside Base44.
- UI File Compilation:** A responsive dashboard screen pulls records from that table to display structural changes and code adjustments cleanly.
- Remote Trigger Step:** An explicit custom action button blocks execution until pressed, pushing updates to the core compiler and clearing the queue upon confirmation.

3. Production Base44 Prompt Configuration Blueprint

To build this exact gatekeeper layout inside Base44 on your desktop, paste the following consolidated blueprint directly into your Base44 AI Builder Chat panel:

"Configure an isolated staging data table named 'pending_build_instructions' containing schemas for 'id', 'instruction_payload', and 'created_at'. Next, design a clean, responsive layout page featuring a markdown code block viewer linked to the latest row of that table. Finally, attach a high-emphasis Action Button designated as 'Approve & Build'. Program its click event behavior to pass the staged payload into the application's native system code compiler, execute a full app deploy, and automatically clear out the staging row variable upon deployment success."

4. Webhook Pipeline Schema Reference

For your integration's reference, your Make.com listener node expects inbound objects structured using this flat JSON payload string:

```
{
  "status": "staged_request",
  "timestamp": "2026-06-17T09:42:00Z",
  "instruction_payload": "Add a user analytics component to the central skincare
inventory view screen"
}
```
